- ① Created a binary search tree using the given data.

then for each node, calculate

Balance factor using formula

$$B.F. = \text{height}(L.S.T.) - \text{height}(R.S.T.)$$

↓
if $\{-1, 0, 1\} \rightarrow$ Balanced

else \rightarrow Unbalanced

so stored these unbalanced nodes in an array `Unbalanced-nodes[]` using counter `k`

Printed these unbalanced nodes : 1 2 3 4

Then height function was created using,
 $\text{height}(t) = 1 + \max(\text{height}(t \rightarrow \text{right}), \text{height}(t \rightarrow \text{left}));$

Here, height for ~~the~~ leaf nodes was taken 1

so height of tree was $\text{height}(\text{Root}) - 1$.

② Took an array input $[] = \{ 1, 2, 3, 4, 5, 6 \}$

Here each element was taken, and inserted in the tree and simultaneously, the tree was checked for Balanced property.

If tree remains balanced, keep inserting.

else, make the tree balanced and then resume inserting.

Step 1.

①⁰

Balanced

Step 2.

①⁻¹

②⁰

Balanced

Step 3.

①^{0-2 = -2}

②⁻¹

③⁰

Unbalanced

anti clockwise rotation

RR Rotation

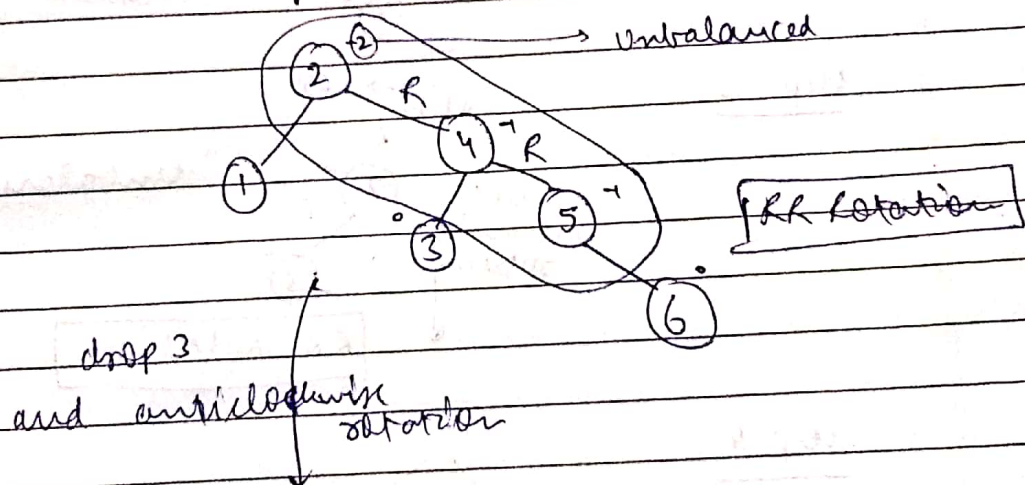

Step 4.

Step 5.

Balanced

Step 6Step 7Step 8Step 9

so this will be the final tree
 with height = 3
 and rotations will be:

RR
RR
RR

Respected Sir,

The first program is running well

But there is some error in the second code.

But still I have uploaded both the codes.

Please help me find my mistake.
